54 **Formation fluid sampler.**

57 An apparatus for taking a sample of formation fluid and obtaining temperature and pressure data when the apparatus is lowered into a well casing or pipe string, said apparatus comprising: a sampling device; a gun perforator; two packers, one positioned above and the other positioned below the sampling device; and valves carried by the sampling device.

## Description

## FORMATION FLUID SAMPLER

This invention relates to an apparatus for taking a sample of formation fluid when lowered into a well casing or pipe string, the apparatus having both a sampling device and a gun perforator.

Present samplers for sampling formation fluid allow materials associated with the drilling of a well, such as drilling muds, and the like to enter the sampler along with the formation fluid.

The object of the present invention is to provide an apparatus for sampling formation fluid so as to obtain an uncontaminated representative sample.

The apparatus according to the invention comprises

- sampling means having wall means dividing the hollow interior thereof into a plurality of chambers axially displaced and adapted to be positioned along the longitudinal axis of said casing, each chamber having at least one port in fluid communication between the inside and outside of said chamber for allowing fluid to enter therein,
- perforating means carried by said apparatus for perforating said casing wall,
- first packer means operatively positioned below and adjacent said sampling means and being adapted to be sealingly set within said casing to form a base for resting said sampling means,
- second packer means operatively positioned above and adjacent said sampling means and being adapted to be sealingly set to form a closed annular space between said sampling means and said casing and between said second packer means and said first packer means,
- lowering pipe means operatively connected to said sampling means for lowering said sampling means within said casing,
- normally-closed pressure-actuable first valve means carried in the wall forming the lowermost chamber of said sampling means for normally closing said port of said chamber,
- normally-closed pressure-actuable second valve means carried by wall means between said chamber and said adjacent lowermost chamber, said second valve means being in fluid communication with said lowermost chamber and sequentially actuable with said first valve means caused by an increase in fluid pressure within said lowermost chamber, and
- normally-closed pressure-actuable third valve means carried by the outer wall forming said chamber above and adjacent said lowermost chamber, said third valve means operatively engageable with said second valve means to open said port of said chamber to allow formation fluid to enter said chamber.

An advantage of the present invention is that a representative sample of the formation fluid can be obtained after removing contaminating fluid from the sampling area of a well borehole.

Another advantage of this invention is that the number of production tests and core samples taken to obtain formation fluid samples is reduced.

A further advantage of this invention is that it can

be used in most sizes of casing or bore holes and does not require specialized running equipment.

An additional advantage is that the well is killed with drilling mud when the top packer is released.

For a better understanding of the invention, its operating advantages and specific objects obtained by its uses, reference should be made to the accompanying drawings and descriptive matter in which there are illustrated preferred embodiments of the invention.

Figure 1 is a diagrammatic view of an apparatus for sampling formation fluid.

Figure 2 is a cross-sectional schematic view of the two lowermost chambers of the apparatus.

Referring to Figure 1 of the drawing, an apparatus for sampling formation fluid may comprise sampling means 10 lowered by pipe means, such as a running pipe string 11, said sampler 10 having wall means 12 and 13 dividing the hollow interior thereof into a plurality of chambers 14, 15, and 16. The chambers 14, 15, and 16 are axially displaced and adapted to be positioned along the longitudinal axis of a well casing or pipe string 18. Each chamber 14, 15, and 16 has at least one port 20, 22 and 23, respectively, in fluid communication between the inside of the chambers and the space outside thereof.

A packer 34, such as a rotation set packer, operatively positioned below and adjacent the sampling device 10 and being adapted to be sealingly set forms a base for resting the sampling device 10 and anchoring means for the apparatus.

Another packer 35 operatively positioned above and adjacent the sampling device 10 and being adapted to be sealingly set forms a closed annular space 24 between the sampling device 10 and the casing 18 and between the lower packer 34 and the upper packer 35.

A pressure-actuable perforating means 40, such as a gun perforator, is carried by the apparatus to perforate the casing wall 18. The perforator is activated in a manner well known to the art, such as by dropping a weight (not shown) to perforate the casing wall 18.

Referring to Figure 2 of the drawing, a port 20 is normally-closed by a pressure-actuable valve assembly 25 carried in the wall forming the lowermost chamber 14 of the sampling device 10. Another port 21 in fluid communication between chambers 14 and 15 is normally-closed by a pressure-actuable valve assembly 26 carried by the wall means 12 between chambers 14 and 15. A pressure-actuable valve assembly 26 is sequentially actuable with the valve assembly 25 caused by an increase in fluid pressure within the lowermost chamber 14.

Port 22 is normally-closed by a pressure-actuable valve assembly 27, such as a sliding piston valve, carried by the outer wall forming chamber 15. The valve assembly 27 is operatively engageable with the valve assembly 26 to open the port 22 of chamber 15 to allow formation fluid to enter into the

chamber 15.

In operation the apparatus is lowered into the well 18 on a running pipe string 11 to a selected depth where formation fluid is to be sampled. The packers 34 and 35 positioned above and below the apparatus are actuated to seal against the inner wall of the casing 18 to form a closed annular space 24 between the sampling device 10 and the casing wall 18 and between the packer 34 and 35. Fluid from a source (not shown), such as a vessel on the ocean surface, may be pumped down the running pipe string 11 and through the circulation port 17 to remove any debris on or near the firing head (not shown) of the gun perforator 40.

The gun perforator 40 is activated in a manner well known to the art, such as by pumping high pressure fluid down the running pipe string 11 to impact the firing head (not shown) of the perforator 40. Upon activating the gun perforator 40 so as to perforate the casing wall 18, the valve assembly 25 is actuated thereby allowing fluid within the closed annular space 24 and formation fluid to enter the lowermost chamber 14 first. Preferably, the volume of chamber 14 should be at least substantially equal to that of the volume of the annular space 24 so as to collect and confine fluids in the annular space other than formation fluid, such as drilling mud, to the lowermost chamber 14.

As the fluid pressure increases in chamber 14, the valve assembly 26 opens port 21. The valve assembly 27, being operatively engageable with the valve assembly 26, opens port 22 to allow formation fluid to enter chamber 15. As the fluid pressure increases in chamber 15, formation fluid would enter chamber 16 upon the opening of a pressure-actuable valve 23 in the same manner as described for chamber 15.

After the formation fluid sample is obtained, the apparatus is removed from the casing 18 using the running pipe string 11 to raise the apparatus to the ocean surface or ground level in a manner well known to the art.

Additionally, temperature and pressure data within the apparatus can be obtained in a manner well known to the art, such as by any suitable gauge which is diagrammatically represented as 30 in Figures 1 and 2.

below and adjacent said sampling means and being adapted to be sealingly set within said casing to form a base for resting said sampling means,

- second packer means operatively positioned above and adjacent said sampling means and being adapted to be sealingly set to form a closed annular space between said sampling means and said casing and between said second packer means and said first packer means,

- lowering pipe means operatively connected to said sampling means for lowering said sampling means within said casing,

- normally-closed pressure-actuable first valve means carried in the wall forming the lowermost chamber of said sampling means for normally closing said port of said chamber,

- normally-closed pressure-actuable second valve means carried by wall means between said chamber and said adjacent lowermost chamber, said second valve means being in fluid communication with said lowermost chamber and sequentially actuable with said first valve means caused by an increase in fluid pressure within said lowermost chamber, and

- normally-closed pressure-actuable third valve means carried by the outer wall forming said chamber above and adjacent said lowermost chamber, said third valve means operatively engageable with said second valve means to open said port of said chamber to allow formation fluid to enter said chamber.

2. The apparatus of claim 1 wherein said lowermost chamber includes a volume at least substantially equal to that of the enclosed annular space outside the sampling means and between said first and second packing means.

3. The apparatus of claim 1 wherein the lowermost chamber contains pressurized gas.

4. The apparatus of claim 1 wherein said chambers include fourth valve means for controlled removal of pressure and formation fluid when said apparatus is raised to the surface.

5. The apparatus of claim 1 wherein at least one chamber includes means for determining pressure and temperature and obtaining a reading of the maximum pressures and temperature within the well.

## Claims

1. An apparatus for taking a sample of formation fluid when lowered into a well casing or pipe string, said apparatus comprising:

- sampling means having wall means dividing the hollow interior thereof into a plurality of chambers axially displaced and adapted to be positioned along the longitudinal axis of said casing, each chamber having at least one port in fluid communication between the inside and outside of said chamber for allowing fluid to enter thereinto,

- perforating means carried by said apparatus for perforating said casing wall,

- first packer means operatively positioned
